Week 1 Coding Challenge Summary

Oct 17, 2026 · @Robert

This week I set up Claude Code, my AI coding helper, with a toolkit of **10 skills** for designing and building web and mobile apps, and I checked every skill for safety before adding it.

What is a skill?

A skill is like a recipe card for Claude Code. It holds instructions (and sometimes small helper scripts) for one kind of task. When I open the project, Claude Code loads the skills, and when a task matches a skill, it follows that skill's recipe. This makes its work more consistent and closer to expert practice.

What happens when I give Claude Code a task.

The 10 skills I added

Design (4)

Skill	Where it comes from	What it does
frontend-design	Anthropic	Makes deliberate, distinctive choices for fonts, colors and layout instead of generic defaults
web-design-guidelines	Vercel	Reviews screens against web interface rules for accessibility and good UX
ui-ux-pro-max	NextLevelBuilder	A searchable library of styles, color palettes, font pairings and UX rules

Skill	Where it comes from	What it does
design-taste-frontend	Taste Skill	Art direction for websites, based on a study of 247 award-winning sites

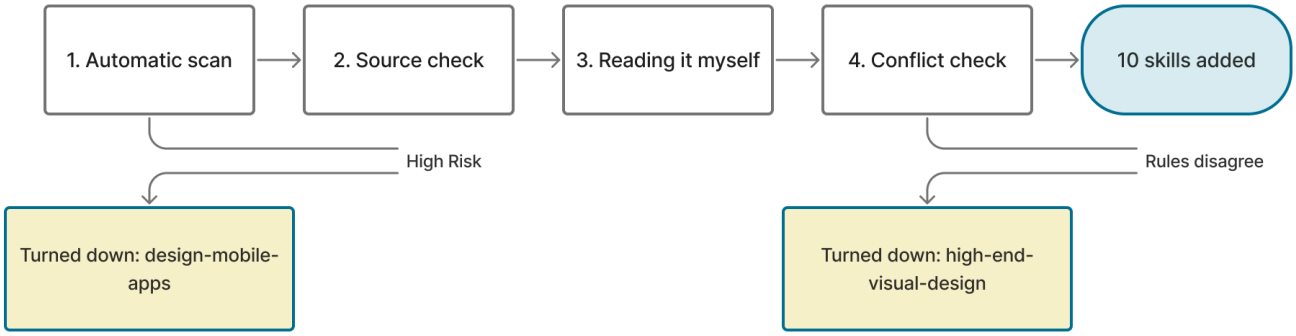

Coding (6)

Skill	Where it comes from	What it does
vercel-react-best-practices	Vercel	Keeps React and Next.js apps fast
react-native-best-practices	Callstack	Keeps phone apps smooth: speed, memory, lists and animations
supabase	Supabase	Back-end work (database, logins, storage) with a security checklist
systematic-debugging	Superpowers	Finds the real cause of a bug before trying a fix
verification-before-completion	Superpowers	Makes Claude run tests and show proof before saying work is done
webapp-testing	Anthropic	Tests web apps in a browser: clicks, screenshots and error logs

How I checked each skill for safety

Skills run with the same permissions as Claude, so a bad skill could cause harm. Every skill went through four checks before I added it:

1. **Automatic scan:** the installer rates each skill's risk using Gen, Socket and Snyk.
2. **Source check:** I made sure it came from the official publisher, not an unofficial copy.
3. **Reading it myself:** I read every instruction file and searched the scripts for network calls, file deletion or requests for passwords.
4. **Conflict check:** I made sure a new skill doesn't contradict the ones already installed.

The path each skill took. Ten made it through, and two were turned down.

Eight skills were rated Low risk. Two official skills (supabase and webapp-testing) were rated Medium, which I accepted because the flagged behavior is exactly their job: looking up Supabase's documentation, and starting a local test server.

Skills I turned down

Skill	Why I removed it
design-mobile-apps	Rated **High Risk**. It sends app descriptions to an outside paid service, needs an API key, and came from an unofficial account. I never added it.
high-end-visual-design	Low risk, but its rules **conflicted** with my other design skills (for example, all-caps labels and fade-ins on every section, which the other skills treat as signs of generic AI design). I removed it to keep the guidance consistent.

What I learned

- More skills isn't always better: skills that disagree can confuse the AI, so the set has to fit together.
- A security rating is a starting point. Reading the skill myself showed *why* it was flagged and whether that was acceptable.
- Recording each skill's exact source and version (in `skills-lock.json`) makes the setup easy to repeat and check.

Where to find it

The skills, a README with every source, and the full safety review are in the **Week 1 - Coding Challenge** folder of my GitHub repository: github.com/willsrobjr124/AI-Development-Residency.
